(54) Title: ANTAGONIST OF MELANIN CONCENTRATING HORMONE AND THEIR USES

(I)

(57) Abstract: The present invention relates to the antagonism of the effects of melanin-concentrating hormone (MCH) through the melanin concentrating hormone receptor which is useful for the prevention or treatment of eating disorders, weight gain, obesity, abnormalities in reproduction and sexual behavior, thyroid hormone secretion, diuresis and water/electrolyte homeostasis, sensory processing, memory, sleeping, arousal, anxiety, depression, seizures, neurodegeneration and psychiatric disorders. The present invention is directed to the compounds of formula (I).

## ANTAGONIST OF MELANIN CONCENTRATING HORMONE AND THEIR USES

Technical Field

The present invention relates to the antagonism of the effects of melanin-concentrating hormone (MCH) through the melanin concentrating hormone receptor which is useful for the prevention or treatment of eating disorders, weight gain, obesity, abnormalities in reproduction and sexual behavior, thyroid hormone secretion, diuresis and water/electrolyte homeostasis, sensory processing, memory, sleeping, arousal, anxiety, depression, seizures, neurodegeneration and psychiatric disorders.

Background of the Invention

Obesity is a major cause and contributor to health problems such as type II diabetes, coronary heart disease, increased incidence of certain forms of cancer, and respiratory complications. It is a disease that is increasing at an alarming rate due to increased availability of high-fat diets, genetic susceptibility, and a more sedentary way of life in modern society. Obesity can be defined as weight gain resulting from a mismatch of energy intake and energy expenditure. Food intake and energy metabolism are regulated, in part, by the interaction of neuropeptides and their receptors. Recently, the role that the hormone leptin plays in controlling appetite has been elucidated.

Leptin is a peptide hormone produced by fat cells, regulating both food intake and metabolism by acting on leptin receptors in the hypothalamus. Increased fat stores leads to increased secretion of leptin, resulting in a signal to the hypothalamus to decrease food intake, whereas decreases in adiposity result in lower leptin levels and a stimulation of food intake. Melanin-concentrating hormone (MCH) has been identified as an orexigenic peptide that counterbalances the activity of leptin.

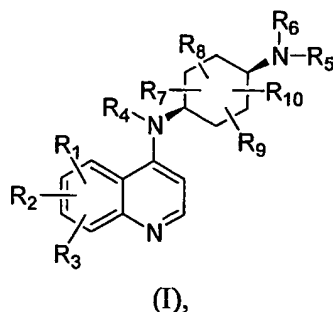

MCH is a cyclic 19 amino acid neuropeptide expressed in the zona incerta and lateral hypothalamus in response to both energy restriction and leptin deficiency. MCH is known to stimulate feeding when injected into the lateral ventricle of rats and the mRNA for MCH is upregulated in the hypothalamus of genetically obese mice (ob/ob) and in fasted control and ob/ob animals. Mice lacking MCH are hypophagic and lean with increased metabolic rate, whereas animals over-expressing MCH gain excess weight on both standard and high fat diets. MCH is thought to have effects on other nervous system functions as well (Nahon JL., The melanin-concentrating hormone: from the peptide to the gene. Crit Rev Neurobiol 8:221-

262, 1994). An orphan G-protein coupled receptor (GPCR) was recently identified as a receptor for MCH.

Although there exists current pharmacologic therapies used to treat obesity, none of the current therapies achieve the U.S. Food and Drug Administration criteria for benefit measured by a 5% difference in mean weight loss, as weight loss efficacy is diminished by reduction of patient adherence to pharmacological therapy due to side effects of the drugs. Some of the side effects associated with current therapies include increased heart rate and blood pressure, and uncontrolled excretion of fat in stools. Thus, there exists a medical need for agents capable of preventing or treating eating disorders, weight gain and obesity, that at the same time, have improved efficacy and safety.

Injectable preparations of the present compounds comprise sterile, injectable, aqueous and oleaginous solutions, suspensions or emulsions, any of which can be optionally formulated with parenterally suitable diluents, dispersing, wetting, or suspending agents. These injectable preparations can be sterilized by filtration through a bacterial-retaining filter or formulated with sterilizing agents which dissolve or disperse in the injectable media.

Antagonism of the effects of MCH through the MCH receptor by the compounds of the present invention can be delayed by using a liquid suspension of crystalline or amorphous material with poor water solubility. The rate of absorption of the compounds depends upon their rate of dissolution which, in turn, depends on their crystallinity. Delayed absorption of a parenterally administered compound can be accomplished by dissolving or suspending the compound in oil. Injectable depot forms of the compounds can also be prepared by microencapsulating the same in biodegradable polymers. Depending upon the ratio of compound to polymer and the nature of the polymer employed, the rate of release can be controlled. Depot injectable formulations are also prepared by entrapping the compounds in liposomes or microemulsions which are compatible with body tissues.

Solid dosage forms for oral administration of the present compounds include capsules, tablets, pills, powders, and granules. In such forms, the compound is mixed with at least one inert, therapeutically suitable excipient such as a carrier, filler, extender, disintegrating agent, solution retarding agent, wetting agent, absorbent, or lubricant. With capsules, tablets, and pills, the excipient can also contain buffering agents. Suppositories for rectal administration can be prepared by mixing the compounds with a suitable non-irritating excipient which is solid at ordinary temperature but fluid in the rectum.

The present compounds can be micro-encapsulated with one or more of the excipients discussed previously. The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric and release-controlling. In these forms, the compounds can be mixed with at least one inert diluent and can optionally comprise tableting lubricants and aids. Capsules can also optionally contain opacifying agents which delay release of the compounds in a desired part of the intestinal tract.

Transdermal patches have the added advantage of providing controlled delivery of the present compounds to the body. Such dosage forms are prepared by dissolving or dispensing the compounds in the proper medium. Absorption enhancers can also be used to increase the flux of the compounds across the skin, and the rate of absorption can be controlled by

providing a rate controlling membrane or by dispersing the compounds in a polymer matrix or gel.

Disorders caused or exacerbated by MCH are treated or prevented in a patient by administering to the patient, a therapeutically effective amount of compound of the present invention in such an amount and for such time as is necessary to achieve the desired result. The term "therapeutically effective amount," refers to a sufficient amount of a compound to effectively ameliorate disorders mediated by MCH, by antagonizing the effect of MCH through the MCH receptor at a reasonable benefit/risk ratio applicable to any medical treatment. The specific therapeutically effective dose level for any particular patient will depend upon a variety of factors including the disorder being treated and the severity of the disorder; the activity of the compound employed; the specific composition employed; the age, body weight, general health, sex, and diet of the patient; the time of administration, route of administration, rate of excretion; the duration of the treatment; and drugs used in combination or coincidental therapy.

The total daily dose of the present compounds in single or divided doses can be in amounts, for example, from 0.01 to 50 mg/kg body weight or more usually from 0.1 to 25 mg/kg body weight. In general, treatment regimens comprise administration to a patient in need of such treatment from about 10 mg to about 1000 mg of the compounds per day in single or multiple doses.

#### Determination of Biological Activity

##### Assay for release of intracellular calcium:

Activation of the melanin concentrating hormone receptor (MCHR) by MCH induces the release of  $\text{Ca}^{++}$  from intracellular stores. This intracellular calcium release is measured using a fluorometric imaging plate reader (FLIPR™, Molecular Devices Corp.) in conjunction with the  $\text{Ca}^{++}$ -sensitive dye Fluo-4. Release of  $\text{Ca}^{++}$  from intracellular stores causes an increase in fluorescence of the dye that is proportional to  $\text{Ca}^{++}$  concentration. Briefly, the assays are performed as follows. HEK293 cells expressing the murine MCHR are plated overnight at 50,000 cells/well in 96-well plates. The following day, culture medium is removed and replaced with 100  $\mu\text{l}$ /well of D-PBS (+glucose and sodium pyruvate) containing 2.5  $\mu\text{M}$  Fluo-4AM (Molecular Probes), 0.01% Pluronic F-127 and 2.5 mM probenecid. Cells are loaded with the Fluo-4 dye for at least one hour at room temp. After

loading, the cells are washed gently to remove extracellular dye and 100  $\mu$ l of D-PBS (+glucose and sodium pyruvate) is added to each well. Test compounds are prepared at 40  $\mu$ M in 4% DMSO. The cell plate is placed in the FLIPR™ and 50  $\mu$ l/well of test compound is delivered. The calcium signal is followed for 3 minutes to assay for potential agonist activity by the test compounds. Then 50  $\mu$ l/well of 12 nM human MCH (in D-PBS containing 0.1% BSA) is added and the ligand-induced calcium signal is followed for an additional 3 minutes. Antagonist activity as determined by the test compounds ability to inhibit MCH induced  $\text{Ca}^{++}$  flux is calculated as % inhibition as described by the following formula:

$$\% \text{ inhibition} = (1 - ((fTC - fB) \div (fMCH - fB))) \times 100.$$

fTC = MCH-induced fluorescence in the presence of test compound;

fMCH = MCH-induced fluorescence in the absence of test compound;

fB = Baseline fluorescence.

MCH (3 nM) usually elicits a response of 30,000 – 40,000 relative fluorescence units (RFU) with a baseline of ~1000 RFU. Fluo-4 fluorescence is measured at 488 nm, with an exposure of 0.40 sec. and F-stop = 2.0 and the laser set at 0.40-0.60 W constant light output.

The compounds of the present invention inhibit MCH induced fluorescence at a dose of 10  $\mu$ M. In a preferred range, compounds of the present invention inhibit MCH induced fluorescence in a range of 75-100% inhibition of MCH at a dose of 10  $\mu$ M. In a more preferred range, compounds of the present invention inhibit MCH induced fluorescence in a range of 90-100% inhibition of MCH at a dose of 10  $\mu$ M.

#### Assay for the inhibition of MCH binding to MCHR:

1  $\mu$ g per well of cell membrane preparations of CHO-K cells expressing the human MCHR1 is added to a v-bottom micro titer plate (Costar). The well volume is brought up to 89  $\mu$ l using binding buffer (25mM Hepes pH 7.4, 1 mM  $\text{CaCl}_2$ , 5 mM  $\text{MgCl}_2$ , 0.5% BSA). 1  $\mu$ l of test compound, dissolved in 100% DMSO, is next added to the wells for a final concentration of 2  $\mu$ M followed by 10  $\mu$ l of  $^{125}\text{I}$ -MCH (NEN). The final concentration of  $^{125}\text{I}$ -MCH in each well is 50 pM. The plate is then placed on a titer plate shaker for 1 hour at room temperature. The samples are then transferred to a 0.1% PEI (Polyethylenimine, Sigma) treated glass fiber filter plate (Packard) using a Packard Filtermate Harvester. The filter plate is washed three times using 200 $\mu$ l wash buffer (Binding buffer without BSA and with 0.5M NaCl). Microscint 20 (Packard) is added to all wells and the plate is sealed with Topseal A (Packard). CPM is measured from the plate using a microplate scintillation counter (Topcount, Packard).

The compounds of the present invention inhibit binding of  $^{125}\text{I}$ -MCH to human MCHR1 at a dose of 2  $\mu$ M. In a preferred range, compounds of the present invention inhibit binding of  $^{125}\text{I}$ -MCH to human MCHR1 in a range of 75-100% inhibition of  $^{125}\text{I}$ -MCH at a

dose of 2  $\mu$ M. In a more preferred range, compounds of the present invention inhibit binding of  $^{125}$ I-MCH to human MCHR1 in a range of 90-100% inhibition of  $^{125}$ I-MCH at a dose of 2  $\mu$ M.

As shown in Scheme 8, compounds of formula (4) can be reacted with compounds of formula (17) (wherein B is aryl, arylalkenyl, aryloxyalkyl, biarylalkyl, cycloalkyl or heterocycle; A is absent or alkylene) in the presence of a base to provide compounds of formula (18). Typical bases include but are not limited to di-isopropylethylamine or N-methylmorpholine. Typical solvents include but are not limited to tetrahydrofuran and N,N-dimethylformamide and reaction times are between 4 and 16 hours.

Alternatively, the synthesis of a compound of formula (18) can be achieved in a

reverse fashion by reacting compounds of formula (17) with compounds of formula (2a) (P is a nitrogen protecting group which is later removed prior to the next step) using the same reaction conditions as mentioned in Scheme 8. The product would then be treated with compound of formula (1) to provide a compound of formula (18) using conditions listed previously in Scheme 1.

##### N-{4-((7-chloroquinolin-4-yl)amino)cyclohexyl}-3-methyl-2-phenylpentanamide

General procedure: Syntheses were performed using a PE Biosystems (Applied Biosystems) Solaris 530 organic synthesizer. Each of the 48 round bottom flasks was charged with 3 equivalents of PS-dicyclohexane carbodiimide resin (PS-DCC) supplied by Argonaut Technologies. The reaction block was then assembled and placed on the Solaris 530. The acid monomers (0.6 mmol) were each dissolved in *N,N*-dimethylacetamide (DMA) (3 mL). The amine core was dissolved in *N,N*-dimethylacetamide. Solutions of *N*-hydroxybenzotriazole in *N,N*-dimethylacetamide and diisopropylethylamine (DIEA) in DMA were placed on the instrument. The Solaris was primed with DMA then into each of the 48 vials containing PS-DCC resin was added 1.25 equivalents of each monomer solution, HOBt solution (0.75 mL, 1 eq), core solution (0.75 mL, 1 eq) and DIEA solution (0.75 mL, 3 eq). The reactions were heated to 55 °C overnight, checked by LC/MS, and transferred with

## Continuation of Box I.2

The present claims relate to prodrugs which are compounds which are transformed in vivo to the parent compounds of formula (I-II). The claims cover all products having this characteristic or property, whereas the application provides support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT for only a very limited number of such products. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Independent of the above reasoning, the claims also lack clarity (Article 6 PCT). An attempt is made to define the compounds by reference to a result to be achieved. Again, this lack of clarity in the present case is such as to render a meaningful search over the whole of the claimed scope impossible. Consequently, the search has been carried out for those parts of the claims which appear to be clear, supported and disclosed, namely those parts relating to the compounds of formula I or II.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.

## Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:  
Although claims 37-39 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. ☒ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:  
see FURTHER INFORMATION sheet PCT/ISA/210
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

### Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
